### PURPOSE OF THE ABSTRACT

Enzymes collectively display a great breadth of catalytic properties yet are individually confined to one or a few specific catalytic tasks. Despite key advances in enzyme engineering, our capacity to predict the effects of mutations on function remains nebulous. Here we present advances in engineering non-native substrate recognition for biocatalyzed transformation into useful products. We examine cytochrome P450 oxidase from *Bacillus megaterium* (P450 BM3) in its capacity to functionalize C-H bonds. Cost-effective, high-throughput colorimetric screening at the whole-cell level had previously suggested a correlation between the production of indigo and increased substrate promiscuity, in a small number of P450 BM3 variants. We greatly expand the diversity of indigo-producing P450 BM3 variants and demonstrate a correlation with promiscuous aromatic hydroxylation reactions. We look ahead to the potential for large experimental datasets to train smarter design algorithms for enzyme engineering.
